Q3.7.1

The null hypotheses to which the p-values given in Table 3.4 correspond are that advertising budgets of TV, radio, or newspaper does not have an effect on sales. The p-values are high-significant for TV and Radio but not significant for Newspaper, which means TV and Radio are related to the Sales, while the Newspaper shows no evidence that it is related to the Sales in the presence of the other two.

Q3.7.3

a)

ii, males tend to earn higher starting salaries given high GPA.

b)

$\hat{y} = 50 + 20GPA + 0.07IQ + 0.01GPA\ddot{O}IQ$

Plugging in the above equation, $\hat{y} = 137.1$ which gives a salary of $137100

c)

False. To show that GPA/IQ has an impact on the model we need to test the hypothesis $H_0 : \hat{\beta}_4 = 0$ and look at the p-value associated with the t statistic to draw a conclusion.

Q3.7.4

a)

Since the true relationship is linear, we could expect that in any given training data that the RSS would be lower for a linear model than it would be with the cubic.

b)

test RSS for a cubic regression will be higher, (with higher flexibility) because the model will probably have been overfitted to the training data.

With such a high degree of flexibility, the model does its best to account for every single training point, which lead to overfitting on another data set.

c)

If we were to fit a cubic model onto a training set, regardless of how far the true relationship is from linearity, we could probably overfit it nicely with some polynomial and have a lower RSS than we could with a linear regression model.

d)

There is not enough information to tell which test RSS would be lower for either regression given the problem statement is defined as not knowing "how far it is from linear".

Q3.7.15

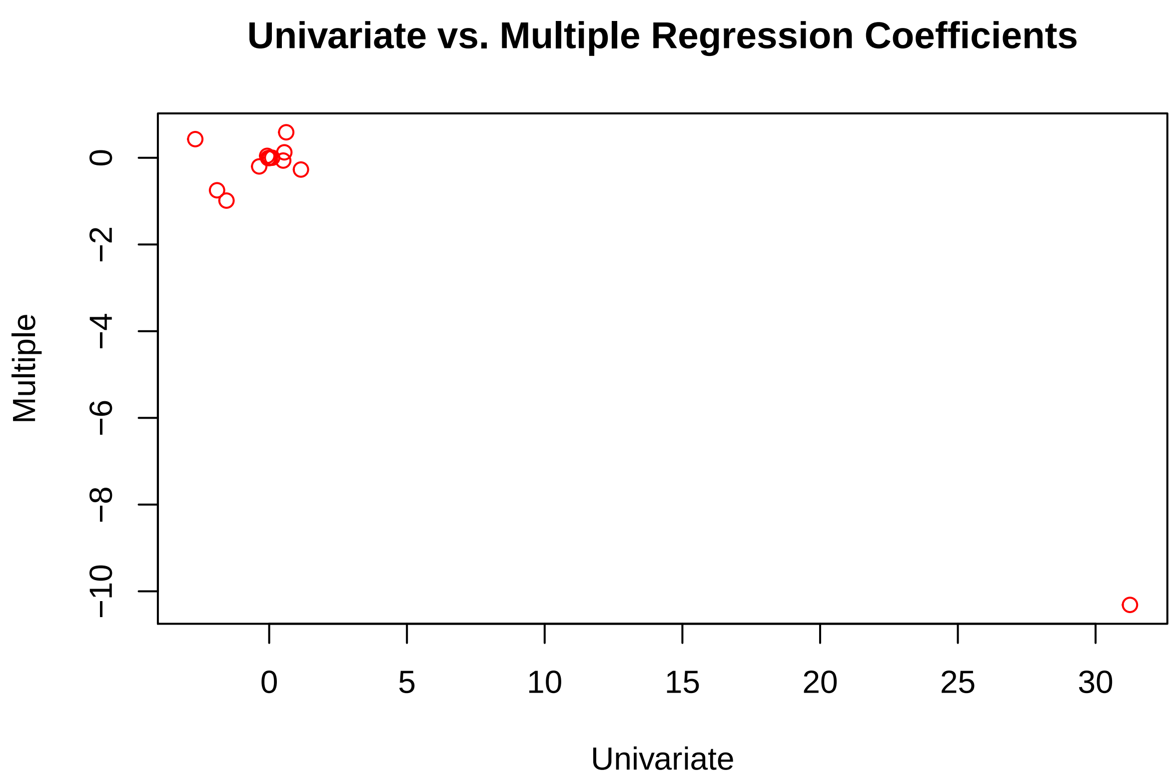
##         black         lstat          medv
##  -0.007537505   0.126211376  -0.198886821
```

```r
plot(univcof, fooBoston$coefficients[2:14], main = "Univariate vs. Multiple Regression Coefficients",
    xlab = "Univariate", ylab = "Multiple", col = "red")
```



In simple regression, the slope term represents the average effect of an increase in the predictor, ignoring other predictors. In contrast, in the multiple regression case, the slope term represents the average effect of an increase in the predictor, while holding other predictors fixed.

With the variables indus, nox, age, dis, ptracio, and medv, there is evidence of a non-linear relationship, as each of these variables squared and cubed terms is found to be statistically signficant (we reject the null hypothesis that the coeffecients on these exponentiated variables are zero). For zn, rm, rad, tax and lstat as predictor, the p-values suggest that the cubic coefficient is not statistically significant
